

(Identity and Access Management)

IAM

USER, GROUP, ROLE

IAM (Identity and Access Management) enables you to securely manage access to AWS services by creating users, groups, and roles. It allows you to define permissions and control who can access specific resources.

- **User:** An individual account in AWS. Each user has a unique identity and can have specific permissions to access different AWS services. Think of a user as a person who logs in with their username and password
- **Group:** A collection of users with similar permissions. Instead of assigning permissions to each user one by one, you can add them to a group and manage permissions for the group as a whole. It's like giving access to a team instead of each member individually.
- **Role:** A set of permissions that can be assigned temporarily to a user, service, or resource. Roles allow you to delegate access without needing to share credentials. Imagine a role like wearing a hat—when you put it on, you get the permissions that come with it.
